**Introduction**

LP02 is a solar radiation sensor that is applied in general observations. It measures the solar radiation received by a plane surface from a 180° field of view angle. This quantity, expressed in W/m², is called “hemispherical” solar radiation. Measuring in a horizontal position it is known as global horizontal irradiance or GHI. Using LP02 is easy. The pyranometer can be connected directly to commonly used data logging systems.

**Sunshine duration**

The World Meteorological Organisation, WMO, defines sunshine hours as “the sum of the time intervals (in hours) during which the direct normal solar irradiance exceeds a threshold of 120 W/m²”. For the most accurate measurement of this quantity tracker-based systems with a pyrheliometer are employed.

**The pyranometric method**

WMO has approved the “pyranometric method” to calculate sunshine duration from pyranometer measurements in WMO-No. 8, Guide to Meteorological Instruments and Methods of Observation. This implies that LP02 may be used, in combination with appropriate software, to measure sunshine duration. The method involves an algorithm which estimates sunshine hours by comparing the 10-minute mean global horizontal irradiance (GHI) with the solar radiation outside the earth’s atmosphere on a horizontal surface at that time and location (G₀).

**Programming**

The algorithm for sunshine duration involves:
- local time (typically from GPS)
- day of the year (typically from GPS)
- geographical coordinates (typically from GPS)
- GHI (from pyranometer)
Benefits of the pyranometric method

Many meteorological stations employ a pyranometer. Not only in that case, but even if a new pyranometer must be purchased, the pyranometric method is much more cost-effective than using a dedicated sunshine duration sensor. A further advantage is that the standardised calibration of pyranometers according to ISO 9847 is applicable. In addition, the instrument stability of pyranometers is much better than that of sunshine duration sensors based on photodiodes. Model LP02 offers a non-stability of < 1 %/yr. Higher class pyranometers such as model SR20 reach < 0.5 %/yr. Competing instruments employing photodiodes attain non-stabilities no better than < 2 %/yr. In summary:

- method is standardised by WMO
- normal pyranometer calibration may be used (no return to factory required)
- better instrument stability than photodiode based sunshine duration sensors
- cost effective (combined with GHI), low-maintenance, easy calibration
- any ISO / WMO compliant pyranometer may be employed

Measurement uncertainty

The measurement uncertainty strongly depends on the measurement site and season. An estimate of achievable accuracy at mid-latitude sites is ± 2 hr/day (k = 2). With optimisation to local conditions this can be improved to ± 0.6 hr/day[1]. Although this does not meet uncertainty requirements for WMO stations (specifying the larger of 0.1 h or 2 %), WMO does states that "individual applications may have less stringent requirements"[2]. Competing instruments, which typically specify an accuracy > 90 %, do not comply to WMO either.

Application note

The relevant algorithm is described in WMO manual WMO-No. 8, Guide to Meteorological Instruments and Methods of Observation, paragraph 8.1.4 b. Hukseflux has issued its own application note. Get a free copy.

* Other pyranometer models may be used as well, non-stability of < 0.5 %/yr is attainable.

Standards

Applicable instrument classification standards are ISO 9060 and WMO-No. 8. Pyranometer calibration is according to ISO 9847.

About Hukseflux

Hukseflux Thermal Sensors, founded in 1993, aims to advance thermal measurement. We offer a complete range of sensors and systems for measuring heat flux, solar radiation and thermal conductivity. We also provide consultancy and services such as performing measurements and designing instrumentation according to customer requirements. Customers are served through the main office in Delft in the Netherlands, and locally owned representations in the USA, China, India and Japan.
